

Modified ALCC

Adrian A. Correndo

03/24/2022

This code was prepared as a tutorial for potential users of the Modified Arcsine-log Calibration Curve (modALCC) detailed in Correndo et al. (2017).

Instructions for users

1. Load your dataframe with soil test value (STV) and relative yield (RY) data.
2. Specify the following arguments into the function `-modALCC()`:
 - (i). 'data' (optional),
 - (ii). soil test value 'STV' and relative yield 'RY',
 - (iii). 'target' of relative yield (e.g. 90%),
 - (iv). desired confidence level (e.g. 0.95 for $1 - \alpha(0.05)$). Used for the estimation of critical soil test value (CSTV) lower and upper limits.
3. Run and check results in a `data.frame`.
4. Check residuals plot, and warnings related to potential leverage points.
5. Adjust curve plots as desired.

Please, refer any question to Adrian Correndo, correndo@agro.uba.ar - correndo@ksu.edu.

Note: RY should be expressed relative to a maximum in order to obtain values bounded at %100. Otherwise, arcsine transformation doesn't work. If RY values $> 100\%$ are found, the function will cap them up to 100% and will display a warning about this.

Last update: 03-24-2022

1. Libraries

```
# Install if needed
# install.packages("easypackages")
# install.packages("devtools")
library(easypackages) # Helps to load packages and install & load them if they are not installed yet.
library(devtools)
packages("readxl") # Open xlsx files
packages("tidyverse", "ggpmisc") # Data wrangling and plots
packages("smatr") # SMA regression analysis for reference
packages("agridat") # For cotton example dataset
```

2. Datasets

```
# Example 1 dataset
data_1 = data.frame("RY" = c(65,80,85,88,90,94,93,96,97,95,98,100,99,99,100),
                   "STV" = c(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15))

# Example 2 dataframe. Imported from csv file
# It can be easily replaced with your own csv file
data_2 = read.csv(file = "data_test.csv")

# Example 3 dataframe. Imported from xlsx file
data_3 = readxl::read_xlsx(path = "data_3.xlsx", sheet = 1)

# Create nested structure as example of multiple datasets
data.all = bind_rows(data_1, data_2, data_3, .id = "id") %>%
  tidyr::nest(data = c("STV", "RY"))
```

3. modALCC() function

```
modALCC <- function(data=NULL, RY, STV, target, confidence){

  # Add a function to cap if there are RY values > 100
  ry <- rlang::eval_tidy(data = data, rlang::quo(ifelse({{RY}} > 100, 100, as.double({{RY}}))) )
  n <- length(ry) # Sample size
  df <- n - 2 # Degrees of freedom
  prob <- 1-((1-confidence)/2) # Probability for t-dist
  tvalue <- qt(p=prob, df = df) # Student-t value
  arc_RY <- asin(sqrt(ry/100)) - asin(sqrt(target/100)) # RY transformation (centered to target)
  ln_STV <- rlang::eval_tidy(data = data, rlang::quo(log({{STV}}) ) ) # STV natural log transformation
  r <- cor(ln_STV, arc_RY, method = "pearson") # Pearson correlation (r)
  p_value <- cor.test(ln_STV,arc_RY, method = "pearson")$p.value # p-value of r
  slope <- sd(ln_STV)/sd(arc_RY) # SMA slope for ln_STV ~ arc_RY
  intercept <- mean(ln_STV) - (mean(arc_RY)*slope) # Intercept
  SMA_line <- intercept + slope * arc_RY # Fitted ln_STV for observed RY

```

4. Fit examples

4.1. Fit ALCC models individually

```
# RY target = 90%, confidence level = 0.95, replace with your desired values

# Data 1
# Using dataframe
fit_example_1 = modALCC(data = data_1, RY = RY, STV = STV, target=90, confidence = 0.95)
```

```
## Warning: 7 STV points exceeded two-times (2x)
## the CSTV for 90%. Risk of leverage. You may consider a sensitivity analysis by
## removing extreme points, re-run the modALCC(), and check results.
```

```
# Alternative using the vectors
#fit_example_1 = ALCC(RY = data_1$RY,STV = data_1$STV, target=90,confidence = 0.95)

fit_example_1
